

A football agent with memory receipts.

Gil predicts, remembers, roasts, and exposes proof. Walrus stores the durable payloads, Walrus Memory stores recall, and Sui stores compact public receipts.

[View system](#)

[Trace proof](#)

Wallet-gated actions, durable memory, public verification.

The system is designed so judges can inspect what was signed, what was stored, and which memory namespace powered each generated answer.

System spine

React SPA on Walrus Sites talks to Gil's Mastra API. The API coordinates memory recall, fixture/profile tools, prediction receipts, output anchoring, and tracking.

1 Wallet signs

Identity and transaction intent.

2 Agent decides

Fixtures, memory, profiles, predictions, roasts.

3 Proof lands

Walrus payload plus Sui receipt.

Walrus Memory

Global schedule and wallet notebooks become recallable context for Gil.

Walrus Blob

Media and output JSON live as durable content-addressed payloads.

Sui Objects

Prediction gates, settlement state, score records, and output pointers stay compact and inspectable.

Generative UI

Chat responses return Markdown plus typed JSON parts for fixture cards, team profiles, and proof receipts.

Outputs live where they can be proved.

The product separates durable content, semantic recall, and public receipts. This keeps the app fast while preserving a verifiable trail for the hackathon judges.

Prediction

Wallet signs

User selects an open match and signs before kickoff.

Sui gate

Prediction object stores owner, match ID, pick hash, and lock state.

Memory note

Gil remembers the take for future callbacks and roasts.

Settlement

Result seed closes the gate, scores the pick, and updates board state.

Chat and roast

Recall context

Agent loads global fixtures, team profiles, player traits, and wallet notebook.

Render answer

Streamdown handles Markdown; typed JSON parts render fixture/profile cards.

Store payload

Important generated output is written to Walrus Blob when publisher is configured.

Anchor proof

Sui OutputRecord stores blob pointer and content hash.

Global memory

Fixture seed

Schedule, groups, teams, venues, flags, squads, and coaches are seeded.

Match changes

Postponements, knockout pairings, and results refresh the same namespace.

Roast traits

Player habits and team folklore are stored as reusable recall facts.

Agent reads

Gil answers from memory, not from hardcoded page copy.

Runtime Tracking

Judges get one surface for package IDs, registry objects, blob links, memory namespaces, site URLs, and explorer links.

Source of truth

Walrus Memory owns recall. Walrus Blob owns payloads. Sui owns compact public proof. The cache is disposable.

Submission fit

Persistent memory, on-chain prediction gates, verifiable output records, and media stored through Walrus.

Perceived speed

A lightweight splash and top progress bar appear before the React bundle finishes and during lazy route transitions.

The architecture is built for inspection, not just presentation.

Open the tracking page, follow the object links, inspect the Walrus blobs, and compare the memory-backed answers.
